

Correlation of Sunrise and Sunset Variations and Their Influence on Day Length

S. Naveera Fatima Rizvi

An exploratory analysis of sunrise and sunset timings from sunrise-and-sunset.com, focusing on their interrelationship and the associated variations in day length.

Distribution of Sunrise, Sunset and Day Length Today?

Day length

The visualizations above illustrate today's sunrise and sunset times, along with the total day length. It would be insightful to compare these results with the solar data from our respective current locations.

Scatter plot and Regression Line for Sunrise and Sunset

Let's explore how sunrise and sunset timings vary with each other

In [9]:

```
# Convert Day Length, Sunset, and Sunrise datetime values into total seconds.
# This numeric format is required for regression modeling (Sunset/Sunrise)
# and for generating the world map visualizations (Day Length)

def to_sec(col):
    """
    This function converts datetime values to seconds

    Input: Series with time values in the datetime format
    Output: Series with time values in seconds
    """
    return col.dt.hour * 3600 + col.dt.minute * 60 + col.dt.second

# Use the to_sec function to create new columns for Day Length, Sunset, and Sunrise in seconds

df["Day_l_sec"] = to_sec(df["Day length"])
df["Sunset_sec"] = to_sec(df["Sunset"])
df["Sunrise_sec"] = to_sec(df["Sunrise"])
```

In [10]:

```
# This function converts predicted regression values from seconds back into datetime format
# This ensures that the regression line can be correctly overlaid on the original scatter
# datetime axes.

def to_dt(total_seconds):
    """
    This function convertes a value in total seconds to its respective datetime value
    Input: time in seconds
    Output: time in datetime
    """
    base_date = dt.datetime(1900, 1, 1)
    # Add the seconds to the base date
    result_time = base_date + dt.timedelta(seconds=total_seconds)
    return result_time

#Regress Sunset (in seconds) on Sunrise (in seconds) and store the preficted values in a column
#Convert the predicted seconds values to datetime using the to_dt function above

reg = smf.ols('Q("Sunset_sec") ~ Q("Sunrise_sec")', df).fit()
df['yhat'] = reg.predict()
df['yhat'] = df['yhat'].apply(to_dt)
```

In [11]:

```
#Plot the scatter plot and regression

fig, ax = plt.subplots(figsize=(15, 8))
xformatter = mdates.DateFormatter('%H:%M') #set format for axes labels

#Define bands depending on the magnitude of daylength according to which the points in the plot
#will vary in size and color

#Band 1: Bottom 5% of the Day length column values. Represented by a value of 1 in a column
df["cols"] = np.where(df["Day length"] <= df["Day length"].quantile(0.05), 1, 6)
#Band 2: 5%-35%. Represented by a value of 2 in the cols column
df["cols"] = np.where((df["Day length"] > df["Day length"].quantile(0.05)) & (df["Day length"] <= df["Day length"].quantile(0.35)), 2, df["cols"])
#Band 3: 35%-55%. Represented by a value of 3 in the cols column
df["cols"] = np.where((df["Day length"] > df["Day length"].quantile(0.35)) & (df["Day length"] <= df["Day length"].quantile(0.55)), 3, df["cols"])
#Band 4: 55%-75%. Represented by a value of 4 in the cols column
df["cols"] = np.where(df["Day length"] > df["Day length"].quantile(0.55), 4, df["cols"])
```

```

df["cols"] = np.where((df["Day length"] > df["Day length"].quantile(0.55)) & (df["Day length"] < df["Day length"].quantile(0.75)) & (df["Day length"] > df["Day length"].quantile(0.75)) & (df["Day length"] < df["Day length"].quantile(0.95)))
#Band 5: 75%-95%. Represented by a value of 5 in the cols column
df["cols"] = np.where((df["Day length"] > df["Day length"].quantile(0.75)) & (df["Day length"] < df["Day length"].quantile(0.95)))
#Band 6: The remaining values are the Top 5%. They're set to the value of 6 in the cols column

#Plot scatterplot
sns.scatterplot(data=df, x="Sunrise", y="Sunset", hue="cols", size="cols", ax=ax, legend='full',

# The following function is for the legend labels
# Define a function which takes in quantile value and finds the associated Day-length value
# corresponding to this quintile

def dayl_to_str(q):

#Formal axes
ax.xaxis.set_major_formatter(xformatter)
ax.yaxis.set_major_formatter(xformatter)

#Format axes ticks
ax.tick_params(axis='x', labelsiz=15)
ax.tick_params(axis='y', labelsiz=15)
#Format axes labels
ax.set_xlabel("Sunrise hour", fontsize=20, fontweight="bold", family='serif')
ax.set_ylabel("Sunset hour", fontsize=20, fontweight="bold", family='serif')

fig.set_facecolor(tuple(np.array([255, 250, 255]) / 255))
fig.tight_layout()

```

```
plt.savefig('correlation_scattermap.png', dpi=300, bbox_inches='tight')
```

The analysis reveals a clear inverse relationship between sunrise and sunset times: later sunrises correlate with earlier sunsets and are linked with shorter day lengths.

In the visualization, cities marked in **deep purple** represent earlier sunrises and later sunsets (the longest days). Conversely, cities marked in **light orange** represent later sunrises and earlier sunsets, corresponding to the shortest day lengths in the dataset.

Plot choropleth world maps for Sunrise, Sunset and Daylengths
